JPEG AI – LEARNING-BASED IMAGE CODING COMMON TEST CONDITIONS

CONTENTS

JPEG AI LEARNING-BASED IMAGE CODING COMMON TEST CONDITIONS

1 Scope

This document describes the Common Test Conditions (CTC) for the JPEG AI image coding experiments. The main objectives of this document are:

- Define the datasets that should be used in the evaluation of learning-based image coding solutions and a procedure for dataset characterization.
- Define the anchors that should be used to comparatively evaluate the performance of learning-based image coding solutions.
- Define the coding conditions, especially the target bitrates that an anchor or learning-based image coding solution should be able to achieve.
- Define the objective quality metrics that can be used to reliably evaluate the decoded images obtained from learning-based image codecs.
- Define the subjective evaluation procedure to perceptually evaluate all decoded images quality, namely the anchors and the learning-based image codecs.

In the current form, these common test conditions should be used to evaluate different aspects of learning-based image codecs. The CTC specification should be followed in all the experiments made by participants.

2 JPEG AI Dataset

The JPEG AI database was constructed to (i) evaluate the performance of state-of-the-art learning-based image coding solutions and (ii) to be used for training, validation and testing of learning-based image coding solutions. This dataset will be made available to all JPEG AI participants. The JPEG AI dataset is organized according to:

- **Training dataset:** The training dataset aims to provide a set of images to create a model suitable for a learning-based image codec solution. However, the proponents may also use a different training dataset provided that it is fully identified in the proposal descriptions and, ideally, made available for future developments.
- **Validation dataset:** The validation dataset aims to provide a set of images to be used during the training to validate the convergence of the training algorithm employed by some learning-based image codec solution.
- **Test dataset (hidden):** The test dataset cannot be used neither for training or for validation and will be used to evaluate the final performance of learning-based image coding solutions. Test images are kept hidden until some appropriate stage, to avoid being used for training. For example, the test dataset for the evaluation of the Call for Evidence submissions was made available only after decoder submission.

The diversity of the images contained in the JPEG AI dataset is high, namely in terms of their characteristics, such as content and spatial resolution. These datasets have the following characteristics:

- Format – PNG images (RGB color components, non-interlaced);
- Spatial resolution – from 256×256 to 8K (8 bit);

- Training/validation/test dataset: 5264/350 images.

The number of images allows for an efficient training/validation and is typically larger than the number of images used in previously available works. The training and validation dataset will be available at sftp://jpeg-cfe@amalia.img.lx.it.pt, password to be given by request (contact: joao.ascenso@lx.it.pt).

The test dataset will only be released after the submission of encoder and/or decoders along with the necessary models (parameters). This dataset should provide a well-balanced set of diverse images that can be used for the evaluation of learning-based image coding solutions.

3 Evaluation Procedure

Objective and subjective quality evaluation of the proposals will be done by at least two independent labs, following well-established procedures and based on the decoded test images provided by each proponent. The submitted code (or binaries) for the decoder, codestreams and decoded images will be used for verification purposes. In Figure 1, the coding pipeline for learning-based image coding solutions, which is rather straightforward, is presented. Proponents may perform encoding with any color space representation, but the input of the encoder and the output of the decoder must be in the PNG (RGB color space) format. Objective image quality will be measured with luminance and color-based metrics and the RGB decoded images will be used for quality evaluation.

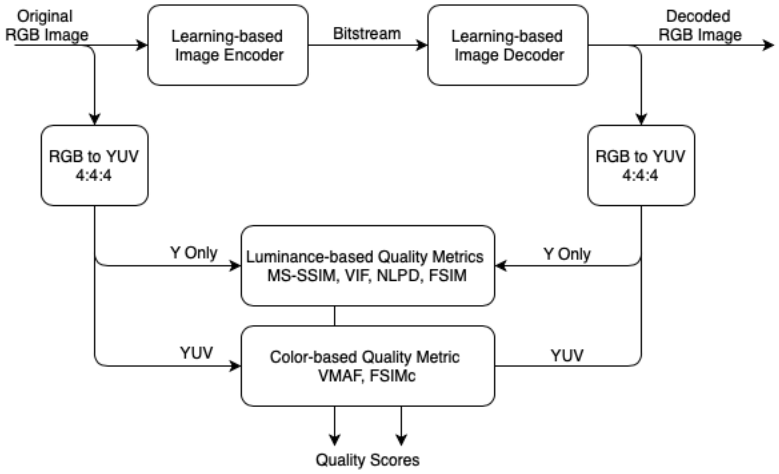

Figure 1 – Encoding-decoding pipeline for learning-based image coding solutions.

4 Target Rates

Target bitrates for the objective evaluations include 0.03, 0.06, 0.12, 0.25, 0.50, 0.75, 1.00, 1.50, and 2.00 bpp. The maximum bitrate deviation from the target bitrate should not exceed 15%. The proponents must declare for every test image which target bitrate their decoder and models can reach, and in case of deviation of the target bitrate, the proposed RD point may not be considered for evaluation. The target bitrates for the subjective evaluations will be a subset of the target bitrates for the objective evaluations and will depend on the complexity of the test images.

The bitrates specified should account for the total number of bits necessary for generating the encoded file (or files) out of which the decoder can reconstruct a lossy version of the entire image. The main rate metric is the number of bits per pixel (bpp) defined as:

$$BPP = \frac{N\_TOT\_BITS}{N\_TOT\_PIXELS}$$

where N_TOT_BITS is the number of bits for the compressed representation of the image and N_TOT_PIXELS is the number of pixels in the image.

5 Objective Quality Evaluation

Objective quality testing shall be done by computing several quality metrics, including MS-SSIM, VMAF, VIFP, NLPD, FSIM, between compressed and original image sequences, at the target bitrates mentioned in the precious Section. This section defines the objective image quality metrics that will be used for the assessment of learning-based image coding solutions.

5.1 MS-SSIM Definition and Computation

Multi-Scale Structural SIMilarity (MS-SSIM) [1] is one of the most well-known image quality evaluation algorithms and computes relative quality scores between the reference and distorted images by comparing details across resolutions, providing high performance for learning-based image codecs. The MS-SSIM [1] is more flexible than single-scale methods such as SSIM by including variations of image resolution and viewing conditions. Also, the MS-SSIM metric introduces an image synthesis-based approach to calibrate the parameters that weight the relative importance between different scales. A high score expresses better image quality.

The source code of this metric can be downloaded at this link:

https://ece.uwaterloo.ca/~z70wang/research/iwssim/.

5.2 VMAF Definition and Computation

The Video Multimethod Assessment Fusion (VMAF) metric [2] developed by Netflix is focused on artifacts created by compression and rescaling and estimates the quality score by computing scores from several quality assessment algorithms and fusing them with a support vector machine (SVM). Even if this metric is specific for videos, it can also be used to evaluate the quality of single images and has been proved that performs reasonably well for learning-based image codecs. Since the metric takes as input raw images in the YUV color space format, the PNG (RGB color space) images are converted to the YUV 4:4:4 format using FFMPEG (BT.709 primaries). A higher score of this metric indicates better image quality.

The source code of this metric can be downloaded at this link:

https://github.com/Netflix/vmaf

5.3 VIF Definition and Computation

The Visual Information Fidelity (VIF) [3] measures the loss of human perceived information in some degradation process, e.g. image compression. VIF exploits the natural scene statistics to evaluate information fidelity and is related to the Shannon mutual information between the degraded and original pristine image. The VIF metric operates in the wavelet

domain and many experiments found that the metric values agree well with the human response, which also occurs for learning-based image codecs. A high score expresses better image quality.

The source code of this metric can be downloaded at this link:

https://live.ece.utexas.edu/research/Quality/VIF.htm

5.4 NLP Definition and Computation

The Normalized Laplacian Pyramid (NLPD) is an image quality metric [4] based on two different aspects associated with the human visual system: local luminance subtraction and local contrast gain control. NLP exploits a Laplacian pyramid decomposition and a local normalization factor. The metric value is computed in the normalized Laplacian domain, this means that the quality of the distorted image relative to its reference is the root mean squared error in some weight-normalized Laplacian domain. A lower score express better image quality.

The source code of this metric can be downloaded at this link:

http://www.cns.nyu.edu/~lcv/NLPyr/

5.5 FSIM Definition and Computation

The feature similarity (FSIM) metric [5] is based on the computation of two low level features that play complementary roles in the characterization of the image quality and reflects different aspects of the human visual system: 1) the phase congruency (PC), which is a dimensionless feature that accounts for the importance of the local structure and the image gradient magnitude (GM) feature to account for contrast information. Both color and luminance versions of the FSIM metric will be used. A high metric value express better image quality.

The source code of this metric can be downloaded at this link:

https://www4.comp.polyu.edu.hk/~cslzhang/IQA/FSIM/FSIM.htm

6 Subjective Quality Evaluation

To evaluate the selected coding solutions, a subjective quality assessment methodology should be used. This type of assessment is especially critical since the type of artifacts that learning-based image compression solutions produce may be significantly different from those in standard image codecs. Subjective quality evaluation of the compressed images will be performed on the test dataset.

The Double Stimulus Continuous Quality Scale (DSCQS) methodology will be used, where subjects watch side by side the original image and the impaired decoded image and both are scored in a continuous scale. This scale is divided into five equal lengths which correspond to the normal ITU-R five-point quality scale, notably Excellent, Good, Fair, Poor and Bad. This method requires the assessment of both original and impaired versions of each test image. The observers are not told which one is the reference image and the position of the reference image is changed in pseudo-random order. The subjects assess the overall quality of the original and decoded images by inserting a mark on a vertical scale. The vertical scales are printed in pairs to accommodate the double presentation of each test picture.

The subjective test methodology will follow BT500.13 [6] and a randomized presentation order for the stimuli, as described in ITU-T P.910 [7] will be used; the same content is never displayed consecutively. There is no presentation or voting time limit. A training session should be organized before the experiment to familiarize participants with artefacts and distortions in the test images. At least, three training images will be used before actual scoring.

The images used for subjective evaluation are a subset of the test dataset images and its number will be selected depending on the number of proposals that will be subjectively evaluated. Moreover, four bitrate points covering a wide range of qualities will be used in the subjective evaluation and an expert viewing session may be organized to select bitrates, namely, to cover a significant range of qualities. The images to be used in the subjective evaluation will correspond to crops of the decoded images such that relevant coding artifacts are included.

To perform the tests, a semi-controlled crowdsourcing setup framework and/or a more controlled lab environment procedure can be used to show the images according to the DSCQS methodology. The semi-controlled crowdsourcing setup has been proven in the past its reliability, i.e. maintains a low variance of the scores [8]. The Amazon Mechanical Turk or other similar platform will be used for crowdsourcing. The QualityCrowd2 [9] software and Amazon Mechanical Turk (or other similar platform) will be used for crowdsourcing. Due to the COVID-19 pandemic, subjective evaluation may be only performed following a crowdsourcing approach.

7 Complexity evaluation

The following complexity metrics should be computed:

- Number of parameters (weights) of the proposed model and their precision.
- Running time with CPU only.
- Running time with GPU enabled.
- DL framework used (e.g. Tensorflow).
- Specifications of the CPU and GPU.

While the first three metrics characterize the coding solution itself, the last two depend on the coding solution implementation and the running platform.

These complexity metrics should be accounted during testing (encoding and decoding processes). The complexity of the training process is less relevant for the purpose of evaluating the learning-based image coding solution and may optionally be reported.

8 Anchors Generation

This section describes the anchor generation process. As anchors, JPEG, JPEG 2000 and HEVC will be used. The list of anchors may be reduced if the number of proposals is too high.

- JPEG (ISO/IEC 10918-1 | ITU-T Rec. T.81)
- JPEG 2000 (ISO/IEC 15444-1 | ITU-T Rec. T.800)
- HEVC Intra (ISO/IEC 23008-2 | ITU-T Rec. H.265)

Information on available software and configurations to be used for these anchors is described next. The target bitrates for the *objective* evaluations are the same as Section 4.

8.1 JPEG Anchor

JPEG does not specify a rate allocation mechanism allowing to target a specific bitrate. Hence, an external rate control loop is required to achieve the targeted bitrate. The following conditions apply:

- Available software: JPEG XT reference software, v1.53
  - Available at http://jpeg.org/jpegxt/software.html.
  - License: GPLv3
- Command-line examples (to use within the rate-control loop):
  - jpeg -q [QUALITY_PARAMETER] -h -qt 3 -s 1x1,2x2,2x2 -oz [INPUTFILE] [OUTPUTFILE]
  - where the h is to optimize Huffman tables -qt 3 to select visually improved quantization tables, -s 1x1,2x2,2x2 to use 420 subsampling and -oz to use trellis quantization.

8.2 JPEG 2000 Anchor

The JPEG 2000 anchor generation should support two configurations: 1) PSNR optimized; and 2) Visually optimized. A target rate can be specified using the –rate [bpp] parameter. The following conditions apply:

- Available software: Kakadu, v7.10.2
  - Available at http://www.kakadusoftware.com.
  - License: demo binaries freely available for non-commercial use
- Command-line examples:
  - **MSE weighted:** kdu_compress -i [INPUTFILE] -o [OUTPUTFILE] -rate [BPP] Qstep=0.001 -tolerance 0 -full -precise
  - **Visually weighted:** kdu_compress -i [INPUTFILE] -o [OUTPUTFILE] -rate [BPP] Qstep=0.001 -tolerance 0 -full -precise -no_weights
  - **Decoding:** kdu_expand -i [INPUTFILE .mj2] -o [OUTPUTFILE .yuv] -precise

8.3 HEVC Intra Anchor

For HEVC Intra, an external rate control loop is required to achieve targeted bitrate. The HEVC RD performance for the target bitrates are obtained with the following conditions:

- Available software: HEVC Test Model (HM 16.16)
  - Available at https://hevc.hhi.fraunhofer.de/svn/svn_HEVCSoftware/tags/HM-16.20+SCM-8.8/
  - License: BSD
- FFMPEG will be used to convert the PNG (RGB) to YUV files following the BT.709 primaries according to:
  - ffmpeg -hide_banner -i input.png -pix_fmt yuv444p10le -vf scale=out_color_matrix=bt709 -color_primaries bt709 -color_trc bt709 -colorspace bt709 -y output.yuv
- Configuration files to be used are available here:
  - https://jpegai.github.io/public/encoder_intra_main_scc_10.cfg

9 Naming Convention for Decoded Images

The PNG decoded files should adhere to the following naming convention:

<TEAMID>_<IMGID>_TE_<RES>_8bit_sRGB_
.png

with:

- TEAMID is the registration team ID attributed with 2 digits
- IMGID is an identification of the image with 5 digits
- TE is a fixed value which represents it is a test image
- RES is the spatial resolution (width x height)
- Bit depth (which must be 8 bits always)
- Color space (which must be sRGB)
- BR target bitrate for decoded images: YXX (e.g. 1.25 bpp would be '125' and 0.05 would be 005)
